OMB No. 0704-0188

Public reporting burden for this collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden to Washington Headquarters Services, Directorate for Information Operations and Reports, 1215 Jefferson Davis Highway, Suite 1204 Arlington, VA 22202-4302, and to the Office of Management and Budget, Paperwork Reduction Project (0704-01888) Washington, D.C. 20503.

13. ABSTRACT *(Maximum 200 words)*

The research training activities started by identifying and picking seismic events from various broadband arrays and networks. The next step was to associate these events with existing catalog locations to build databases of local, regional and teleseismic events which are being used in this research project as well as other seismic verification projects at our institute and also other universities. The data processing aspects included learning to use the CSS 3.0 database format to allow the management of datasets with thousands of events. The seismic processing included identification of local, regional, and teleseismic phases which are essential for seismic discrimination research. This involved learning the TCL/TK language and the application of this knowledge to provide a graphical user interface to build CSS databases. This program is being developed to support field deployments of seismic stations which will ensure the proper documentation of instrument responses, site locations, and calibration parameters. In addition, this software has been used to support deployments of the Wyoming portable broadband seismic and infrasonic experiments, and with all aspects of data assembly, data processing, data distribution to the research community.

This AASERT award was used for Aaron Geddins, a minority undergraduate student at the University of California at San Diego. The AASERT research project was in the Institute of Geophysics and Planetary Physics at the Scripps Institution of Oceanography. As a part of this program, Aaron was required to research areas of local, regional and teleseismic seismology. In this process, it was necessary to gain a thorough knowledge of computer hardware and software, data management, and office administration. Aaron has provided several presentations on his various aspects of his work to IGPP groups.

Aaron's initial task was to spend part of his first year picking arrivals from seismic events following the Mw=6.8 Northridge earthquake of 17 January 1994. In order to do this, he was trained on a program called dbpick. Dbpick allows the user to see the digital display of the waveforms and estimate where the arrivals are. It's the analyst's job to give the precise location of these arrivals and give its amplitude and range. With the collection of this data, Aaron calculated the locations and magnitudes of the seismic events.

After the completion of the Northridge data analysis, Aaron was tasked with learning about what is involved in deploying a seismic station. He learned about the different ways to orient a seismometer, what a datalogger was and how it is set up, how to assemble a solar panel and how to connect it with the datalogger and seismometer, how to use a compass in aligning a solar panel, and how to secure a station from possible vandalism. Knowing the proper way to install a station is vital in order to record seismic events accurately.

With this knowledge of station deployment, Aaron was instructed on how to provide proper documentation for each deployment. This included the preparation of station parameter files which provide a time history of each station's operating parameters. A station parameter file (stapar) is a data file that consists of information such as: latitude, longitude, elevation, sensor serial number, datalogger serial number, sample rate, and other

technical aspects that define the seismic station. The stapar file is necessary in order to keep account of the current condition of the seismic stations. If a component of the station such as the seismometer was replaced, a new stapar file would be created to indicate that change. Another example would be if the researcher would send a technician to the station to change the sample rate. Thus, a new stapar file would be created to show the new values for the fields changed.

After being well versed in picking of arrivals, station deployment, and creating and understanding stapar files, Aaron had the necessary tools to write a computer program named field2db. Field2db is a graphical user interface application written in tcl/tk and is intended to provide a simple interface to input data supplied by field technicians to create or update the appropriate tables in the CSS3.0 database format. Field2db has three main functions, to view stapar files in a much more readable format, create stapar files and database tables from scratch (meaning from a new seismic network), and edit existing database tables. In the past, the best way to view a stapar was on a printout. Even then, there are so many fields that sometimes one can lose track of what information that was in question. Field2db will view a stapar with only selected fields showing. If the user wants to see more fields or specific fields, there is a menu button 'VIEW' that will allow them to do just that. If the user wants to see all the fields in a stapar file, then field2db will supply a horizontal scrollbar in order to view the 'hidden' fields.

The creation of stapar files and database tables is a little more involved process. In this aspect of field2db, the user is asked to fill in information about the seismic network and the stations that make up that network. It has been discovered that most of the data needed to create stapar files and database tables can be produced from logfiles. Logfiles are files that are produced automatically and require no human interference. With this new found discovery, it makes for less data entry for the human user and thus allows for less mistakes in the stapar files and database tables. This feature of field2db is a window-based, menu-driven feature, thus the user will have all the information needed in order to

enter the data. A text window drives the user through the necessary steps and highlights the proper buttons to be clicked. Once the user has entered the proper information, the Build Database button will be highlighted. Once this button is clicked, the database tables will be written. These tables are written in CSS3.0 format and can be viewed by using another program called dbe. The database tables are written by using the datascope utilities which have been developed at the Joint Seismic Program Center at the University of Colorado. Along with logfiles, parameter files are also used to cut down on the amount of entries that a user has to make. For instance, for a given REFTEK datalogger, certain sample rates correspond to certain filters that are to be used. So a user should never have to enter the filters needed to get a certain sample rate to 40 samples per second. This information should be put into a parameter file. The net result is a simple interface which either portable deployments or regional networks can use to generate CSS3.0 database for archiving, data analysis, or data distribution.
